Conclusion

The Bay Waterfront Adaptation and Vulnerability Evaluation (BayWAVE) sea level rise vulnerability assessment examined the exposure, sensitivity, and adaptive capacity of built and natural assets in Marin County. Many of Marin’s essential and beloved shoreline assets are vulnerable to sea level rise and a 100-year storm surge. Key takeaways from this assessment are:

- Everything is connected—impacts to one asset or one community could have regional impacts. Even people who live high and dry could be vulnerable to disruptions along Marin’s shoreline, especially travel to and from work, school, and health services. Thus, asset managers, property owners, elected and appointed officials, government and consultant professionals will all need to work together to strategize for and implement the best possible outcomes.
- Without safeguards, kinks in the utility and transportation networks could impact hundreds of thousands of residents, employees, and visitors as early as the near-term. Disruptions or damages to these networks could be crippling to modern daily life. Few alternative route options are politically or physically viable.
- Areas seasonally impacted now or during king tides could flood almost daily in the near-term.
- Shifts to higher high tides impact public and private ownership under the public trust doctrine requiring hundreds of households to pay fees to the State they do not currently pay.
- Areas on fill and bay mud will face increasing rates of subsidence.
- The majority of low-lying areas, even those protected by levees, could experience tidal impacts after three feet of sea level rise.
- Some of the most vulnerable places are occupied by those with the least amount of resources and abilities.
- San Rafael and small shoreline unincorporated communities in Southern Marin could be the first to experience significant tidal flooding in the near-term.

15-year Expectations

Storm surge flooding could impact 2,500 parcels and 3,800 buildings. These figures amount to six percent of parcels and buildings in the study area. Storm surge flooding, especially combined with stormwater flooding, could impact North Novato at Gnoss Field. Sea level rise flooding could reduce usable living space, and adversely affect tourism, transportation, recreation and natural resources within 15 years. The first threats are to buildings, roads, and original utility systems along the shoreline. Tidal closures and/or damage to roads, and breakdowns utility networks could have regional ripple effects beyond the flooded areas for extended period of time.

In this near-term timeframe, tidal flooding at 10 inches of sea level rise (MHHW) could reach 5,000 acres with 1,300 parcels and 700 buildings, potentially impacting tens of thousands residents, employees, and visitors. These figures amount to two percent of parcels and one percent of buildings in the study area. Monthly tidal flooding could adversely impact San Rafael east of US Highway 101, bayfront Belvedere and Tiburon, Greenbrae, Waldo Point, and Paradise Cay within this time period.
With an additional 100-year storm surge added to sea level rise, the previously impacted acres, parcels, and buildings could face tidal and storm surge flooding. And an additional 3,000 acres, with Black Point on the Petaluma River, lower Santa Venetia, Belvedere around the lagoon, bayfront Corte Madera, bayfront Mill Valley, Marinship in Sausalito, Tamalpais, and Almonte.

Eight miles of road could expect tidal flooding. Many of the flooded intersections already experience storm and king tide flooding. These are:

- The Manzanita area, US Highway 101 at Shoreline Highway,
- Miller Avenue in Mill Valley,
- The Marinship area in Sausalito,
- US Highway 101 in Corte Madera and Larkspur, and
- State Route 37 in Novato.

This is expected to worsen in severity and could be experience daily by near-term scenario 1. Tidal flooding could soon start to regularly reach the Canal area of San Rafael all the way to Interstate 580. Several roads that are now dry may begin to experience seasonal, king tide, and storm surge flooding. These would be roads in Santa Venetia, Tamalpais, Belvedere, Mill Valley, Marin Lagoon of San Rafael, and bayfront Corte Madera and Larkspur.

Water travel infrastructure could be compromised at ferry facilities in Larkspur, Tiburon, and Sausalito preventing commuters from traveling to work. Even if the facilities are able to handle near-term high tides, providing safe parking and access to ferry users could prove challenging. Smaller marinas and boat launches along the bay in Sausalito, Mill Valley, Strawberry, Tiburon, Belvedere, Bel Marin Keys, and Black Point could be flooded out and unusable several months out of the year during high tides. Storm surges can be powerful enough to damage and sink boats. This is especially a concern for residential boats.

Southern Marin Fire Protection and Sausalito Police Department boats are included in the boats harbored in marinas vulnerable to sea level rise. The Castro Fire Station in San Rafael is vulnerable to tidal flooding in the near-term and the California Highway Patrol could expect storm surge flooding in this time period. Most concerning, however; is the potential inability of emergency vehicles to access people and places in danger due to the roads flooded in the near-term.

In addition, the marshlands that buffer the shoreline communities from high tides and storm surges could begin to experience transitions in habitat, especially those in Southern Marin where they are typically bordered by urban development. Consequently, the waters here would get deeper and flood out the existing habitat. This might shift marsh habitat from high marsh to low marsh, low marsh to mud flat, and mud flats to open water. Without adequate light in deeper waters, eelgrass beds would shrink. Collectively, these habitat shifts could have significant impacts on vulnerable species, such as the salt marsh harvest mouse, Ridgway's Rail, or the long-fin smelt.

In 15 years, high tides could threaten Marin's shoreline buildings, roads, and original utility systems. Damage and breakdowns in road and utility networks would impact the entire County, especially Southern Marin. Tidal flooding (red) could reach 5,500 acres, 1,300 parcels, 700 buildings, and 8 miles of road in San Rafael east of State Route 101; bayfront Belvedere and Tiburon, Greenbrae Boardwalk, Waldo Point, and Paradise Cay. A 100-year storm surge (pink) would flood these areas with storm surge flooding, and flood an additional 3,000 acres, 2,500 parcels, 3,800 buildings, and 20 miles of road in North Novato, Black Point on the Petaluma River, lower Santa Venetia, Belvedere Lagoon, bayfront Corte Madera and Mill Valley, Marinship in Sausalito, Marin Lagoon in San Rafael, Tamalpais, and Almonte. Flooded ferry facilities would prevent commuters and visitors from traveling across the Bay. Boating facilities in Sausalito, Mill Valley, Strawberry, Tiburon, Belvedere, San Rafael, Bel Marin Keys, and Black Point may be inaccessible. This is especially a concern for marinas with residential boats and Southern Marin Fire and Sausalito Police boats. The Castro St. Fire Station in San Rafael is vulnerable to tidal flooding, though all emergency professionals would be denied vehicular access to people in vulnerable areas Southern Marin marshlands would shift high marsh to low marsh to mud flat, and eelgrass beds could shrink under deeper darker waters. These habitat shifts would have significant repercussions for plant, insect, fish, and animal species.

**Mid Century Expectations**

In this medium-term timeframe, tidal flooding at 20 inches of sea level rise (MHHW) could reach nearly 7,000 acres, 3,000 parcels, and 2,000 buildings, and impact even more residents, employees, and visitors than in the near-term. These figures amount to two percent of parcels and three percent of buildings in the study area. Monthly tidal flooding could adversely impact the same locations flooded in the near-term, though more severely.

With an additional 100-year storm surge, the previously impacted acres, parcels, and buildings could face tidal and storm surge flooding, and an additional 7,000 acres, with 2,200 parcels and 3,600 buildings could anticipate storm surge flooding. These figures amount to eight percent of parcels and seven percent of buildings in the study area. This is a significant jump in impacted area, likely because many inadequate levees and other shoreline armoring structures could be overtopped at this water level. Storm surge flooding could impact the same locations as in near-term storm surge scenario 2, and extends further inland beyond the marshes of Mill Valley, Strawberry, San Rafael, St. Vincent's, and North Novato.

Eighteen miles of roadway, ten more miles than in the next fifteen years, could expect tidal flooding. Many of the impacted roads are the same as those impacted in the near-term, though much greater lengths could anticipate tidal flooding at MHHW and depths of flooding would increase on segments exposed to flooding in the near-term. Storm surge flooding could reach a total of 62 miles of roadway. Water travel could experience similar outcomes as in the near-term, though the highest high tides and storms surges would cause even more damage than weathered twenty years earlier.

With respect to utilities, pipelines under vulnerable roads, and lateral pipes to vulnerable properties, would become squeezed between rising groundwater and the confining roadway. This could cause pipes to bend and break, and could even damage roadways. In the medium-term, impacts to the North Marin Water District assets would impact water service in Bel Marin Keys and unincorporated Novato. Vulnerable electrical substations, transmission towers and lines, and underground natural gas pipelines along the shoreline would be compromised by flooding and subsidence, and would subsequently affect transportation, sewer,
CONCLUSION

stormwater, food storage, and communications assets, and general public safety.

This twenty inch increase in sea level would continue to shrink trapped habitats in Southern Marin. Storm surges would only exacerbate erosion as well.
Tidal flooding could reach 7,000 acres, 3,000 parcels, 2,000 buildings, and 18 miles of roadway in the same locations impacted in the near-term, though more severely. With a 100-year storm surge, the area vulnerable to tidal flooding would also experience storm surge flooding. An additional 7,000 acres, 2,200 parcels (8% of total), 3,600 buildings (7%), and 40 miles of roadway could anticipate storm surge flooding. Most levees south of Novato are not designed to withstand this level of flooding and would be overtopped. Storm surge flooding would extend further inland beyond the marshy areas of Mill Valley, Strawberry, San Rafael, St. Vincent’s, and North Novato. Water travel could experience similar outcomes as in the near-term, though the highest high tides and storm surges would cause even more damage than weathered twenty years earlier. Pipelines beneath flooded roads could become squeezed between rising groundwater and the roadway, causing pipes to bend and break, and even damage roadways. This is true for PG&E substations, electrical transmission towers and lines, and natural gas pipelines could be bent or broken by flooding, subsidence, and erosion, with far reaching impacts on utilities, buildings, and transportation. This ten inch increase in sea level would continue to shrink trapped beach and marsh habitats in Southern Marin. Shoreline parks and pathways would flood often.
**End of Century Expectations**

In this long-term timeframe, tidal flooding at 60 inches of sea level rise (MHHW) could reach nearly 7,000 acres, 8,000 parcels, and 9,000 buildings, potentially impacting hundreds of thousands of residents, employees, and visitors. These figures amount to 13 percent of parcels and 12 percent of buildings in the study area. Regular tidal flooding could adversely impact the same locations impacted in the near- and medium-terms and significant portions of what would have previously only flooded during a 100-year storm surge. The areas that could now also be tidally flood at this higher high tide are:

- Tamalpais Valley,
- Mill Valley from the Richardson’s Bay shoreline up to and beyond Camino Alto between Miller and East Blithedale Avenues,
- Mill Valley and Strawberry fronting US Highway 101 between Seminary Drive and Tiburon Boulevard,
- Santa Venetia north of N. San Pedro Boulevard,
- Cove Neighborhood, Tiburon,
- Belvedere Lagoon neighborhood,
- Paradise Cay,
- Mariner Cove, Marina Village, Madera Gardens, and major retail centers lining US Highway 101,
- Riviera Circle, Creekside, and Heatherwood neighborhoods, Larkspur,
- Interstate 580 and westward towards Andersen Drive in San Rafael and the community of California Park,
- Marin Lagoon and Peacock Gap neighborhoods, San Rafael,
- Bel Marin Keys northern and southern lagoon areas,
- Hamilton, Vintage Oaks, and pockets of development east of US Highway 101 at Rowland Boulevard and State Route 37 in Novato, and,
- North Novato at US Highway 101 and Binford Road.

In long-term scenario 6, storm surge flooding could occur on nearly 13,500 acres hosting 12,600 parcels with 12,000 buildings. These figures amount to nearly one-fifth of parcels and more than 15 percent of the buildings in the study area. Areas that could anticipate storm surge flooding under scenario 6 conditions are:

- Sausalito west of Bridgeway,
- Marin City neighborhood,
CONCLUSION

- Mill Valley east of East Blithedale Avenue at the Alto Shopping Center,
- Las Gallinas and North San Pedro Boulevard, east of US Highway 101, San Rafael,
- Bayside Acres,
- Country Club, and
- Kentfield.

Tidal and storm surge flooding could cause significant economic losses. Minor storm impacts alone could account for $61 million in 2016 dollars. The market value of vulnerable single-family homes could exceed $20 billion in 2016 dollars. The assessed value, typically less than market value, for all the vulnerable parcels in the study area is $15.6 billion. By the end of the century, these figures would likely be even higher.

One-hundred miles of public and private roadways, or five percent of all road miles in the study area, could be vulnerable to tidal flooding. Roads could simply degrade more quickly, or if flood waters are deep enough, become impassable when tides rise. Lane miles could be more than double this figure. An additional 30 miles of roadway could be vulnerable at 60 inches of sea level rise and a 100-year storm surge.

In addition, several park and rides, several hundred bus stops, and bus transit and SMART rail routes could flood. The San Rafael Transit Center, where the SMART train and nearly all buses stop, is vulnerable in the long-term to sea level rise. High tides. Breakdowns in the transportation network would have major impacts on the economy and daily life functions. In addition, significant safety hazards could cause injury or loss of life.

Flooding at the SASM and Novato Sanitary Wastewater Treatment Plants is a significant vulnerability that could arise, potentially disrupting hundreds of thousands of people. By this time, much of the low-lying shoreline sanitary sewer and stormwater infrastructure could be overrun with tidal waters.

By the end of the century, sea level rise could have direct impacts to Tiburon Fire Station No. 1, Corte Madera Station No. 13, and Novato Atherton Avenue Fire Station. A few emergency shelters in Southern Marin communities could be vulnerable to tidal flooding, and several more could expect 100-year storm surge flooding and may not be available when needed most. By this time, the Central Marin Police Department could have to stave off flood water surrounding the site to reach Larkspur and Corte Madera residents in need.

Southern Marin marshes may no longer exist by the end of the century, destroying the habitat of several shoreline birds and mammals. Northern Marin marshes would become increasingly tidally influenced, with tide water reaching US Highway 101 in Bel Marin Keys and North Novato up the Petaluma River. Typically freshwater marshes west of US Highway 101, for example, Sutton Marsh, could also be subject to damaging salinity impacts. Tidal marsh lands may increase in Northern Marin if they are not prevented from migrating inland.

Finally, all of these assets contain or contribute to the well-being of the region’s cultural, archeological, and historic resources that constitute each community’s sense of place. This is especially a concern for Sausalito, Tiburon, and Novato.

By 2100, tidal flooding could reach nearly 7,000 acres, 8,000 parcels (13%), 9,000 buildings (12%), and 100 miles of road. Higher high tides could adversely impact the locations flooded in medium-terms, and significant portions of the areas that previously suffered storm surge flooding. Tidal flooding would reach beyond the State Routes 101 and 580 in low-lying areas, into Southern Marin’s narrow valleys and creek sides, and over every levee in Marin County. A 100-year storm surge could flood these areas, and an additional 6,500 acres, 4,600 parcels (20% total), 3,000 buildings (15% total), and 30 miles of road, extending to Sausalito west of Bridgeway, Marin City housing, Mill Valley’s Alto Shopping Center, Las Gallinas and N. San Pedro Blvd. in San Rafael, Bayside Acres, Country Club, and Kentfield. Minor building damage could amount to $61 million (2015 dollars). Vulnerable single family homes exceed $20 billion in market value (2015 dollars). Several park and ride, hundreds of bus stops, and bus routes, and SMART rail track, including the San Rafael Transit Center, could experience flooding. Disruptive flooding at the SASM and S2D wastewater treatment plants and pump stations would affect tens of thousands of people. Storm surges could flood Tiburon Fire Station No. 1, Corte Madera Fire Station No. 13, and Novato Atherton Ave. Fire Station. A few emergency shelters in Southern Marin flood at high tide, and many more could be closed during a storm. The Central Marin Police Department may have to navigate deep water to reach Larkspur and Corte Madera shoreline residents. In Southern Marin, mud flats and water would dominate existing marshes. In the north, tidal marshes could expand.

Source: MarinMap, CoSMoS
Table 132 lists the Marin shoreline communities’ vulnerable assets by onset for each community and unincorporated Marin. These assets are vulnerable under the six scenario selected for the BayWAVE process, 10 inches, 20 inches, and 50 inches of sea level rise, and each with a 100-year storm. A significant degree of uncertainty exists as to how soon these increases in sea level could occur because future carbon emissions, a major variable in modeling, are an unknown. However, even if global citizens stabilize carbon emissions, sea level rise would likely continue. Moreover, even if the growing global population reduces carbon emissions to levels where atmospheric concentrations decline, the decline will be slow and sea levels would still likely continue to rise for decades, and hundreds of years could pass before the sea level stabilizes or drops. If emissions continue to increase, the rate of sea level rise is also likely to increase and these assets could be vulnerable sooner than this assessment presents. Because of this uncertainty, this assessment is the first step in an iterative process that will need to be updated as additional science becomes available and adaptation efforts are implemented. The sea level rise preparation process will require consistent monitoring and evaluation to improve modeling assumptions and ensure preparation efforts are effective and efficient.

Built and natural features in Table 132 are many assets to be addressed in adaptation planning. Some communities are already adapting to sea level rise. Efforts in Waldo Point, Strawberry, Las Gallinas, the Redwood Landfill, and others are already working to decrease vulnerability to higher tides and subsidence. Implementing additional adaptation measures may require new institutional, legal, and financing arrangements, engineering measures, and other incremental actions property owners and government entities can take. These measures and sea levels on the coast must be monitored and evaluated to inform need and effectiveness of these types of strategies. This vulnerability assessment lays the informational foundation for adaptation planning and implementing the necessary measures to protect, accommodate, retreat, or preserve existing geographies.

Combined with potential losses in West Marin due to potential sea level rise, the impacts to Marin County will be significant across all asset categories. The image to the left combines estimates for land area that would be lost at MHHW across the near-term, 2030, the medium-term, 2050, and the long-term, 2100 scenarios applied to Western and Eastern Marin.

With the Vulnerability Assessment complete, Marin County, municipal, and special district governments, and other essential service providers, non-profits, and property owners have a glimpse of a potential future with higher tides. By the end of the century, sea level rise could significantly alter daily life in Marin County. The Vulnerability Assessment summarizes the worst case scenario with business as usual. Fortunately; business as usual is already changing with significant restoration, conservation, and redevelopment efforts along the Marin shoreline that show promise for the coming decades.

---

Sea level rise is a moving target, and likewise, adaptation efforts will need to keep pace and be able to adjust more quickly than the seas rise. Moving forward, government officials, residents, and professionals will have to weigh the options to protect, reinvent, or relocate existing assets where feasible, or at worst, what assets cannot be saved. These decisions will trigger several other challenging questions, especially in an area where developable land is not readily available, demand for housing is high, and new development can be politically challenging. Getting through these questions, entering the study and planning phases, getting approvals, securing funding, and implementing improvements can be a multi-year to multi-decade process. Because of this, it is imperative that sea level rise preparation planning and implementation is strongly supported and undertaken promptly and continuously in the coming decades to ensure the County and its residents are prepared for and safe from sea level rise. The future phases of BayWAVE will explore these options further and provide the basis for continued discussion, planning, and action.

Appendix A: Vulnerability Assessment Interview Tool

BayWAVE Program
Bay Waterfront Adaptation and Vulnerability Evaluation
Asset Vulnerability Assessment Tool and Script

Managing Agency: ___________________________ Date: ______________
Asset Manager Name(s): ______________________ Phone: ____________
Asset: _________________________________

This assessment tool will be used to gather information on how sea level rise can impact public assets on Marin’s bayside shoreline. Thank you for taking the time to respond to this series of questions. At most, it could take 1 hour to answer 30 questions. The tool asks several yes or no and short answer questions, followed by ranking degrees of sensitivity, adaptive capacity, and risk factors associated with sea level rise and storm surges. Lastly, the tool asks for preliminary ideas for adaptation. Let’s begin.

The first set of questions may be useful in the planning process and will help get us thinking about sea level rise and storm surge preparation.

1. Are there efforts underway to address SLR/GIS (emergency or climate change efforts) at your agency or organization?
   - No
   - Yes __________________________

2. What is your level awareness of sea level rise?
   - None
   - Low, heard/read of SLR
   - Moderate, involved in training/project
   - High, expert __________________________

3. What is your general workplace’s awareness of sea level rise?
   - None
   - Low, heard/read of SLR
   - Moderate, involved in training/project
   - High, expert __________________________

4. Please describe the current physical condition of the asset: Are there existing stresses, are they likely to improve/worsen?

5. Has the asset been disrupted in the past due to an unplanned stress e.g., weather-related closure, emergency repair, strike?
   - No
   - Yes. How long did disruption last? __________________________

5a. Was the asset able to continue functioning?
   - No
   - Partially
   - Yes __________________________

6. When was the last repair or update? ________________

7. Is any major maintenance or repair planned?
   - No
   - Yes, when __________________________

8. Were/are any permits from state and regional agencies, such as the Bay Conservation and Development Commission (BCDC), required to do conduct needed work in questions 5, 6, 7 or other flood prevention measures? If yes, please describe your experience with the permit process.

For the second set of questions, please respond about how the following sea level rise and storm surge could impact the asset. Impacts the asset could be exposed to include:

- Permanent flooding
- Temporary flooding
- Rising water table
- Saltwater Intrusion/corrosion
- High wind Impacts
- Beach/cliff erosion
- Habitat shifts (natural resource assets only)

The following questions address sensitivity, adaptive capacity, adaptation ideas, and risk for each. For the sensitivity assessment, sensitivity is defined as the degree an asset could be damaged or the service it provides disrupted. Please indicate if the asset will be sensitive for each exposure according to these levels:

BayWAVE Vulnerability Assessment Tool | 1
No Sensitivity: Not impaired, damaged, or disrupted
Low Sensitivity: Minimally impaired, damaged, or disrupted. The asset may require minor repairs or suffer minimal disruption.
Medium Sensitivity: Somewhat impaired, damaged, or disrupted. The asset may require repairs and be able to maintain most functions.
High Sensitivity: Greatly impaired, damaged, or disrupted with complete loss or shutdown. The asset will require significant repairs and disruption could impact public health and safety.
Maximum Sensitivity: Permanent loss or disruption.

Using the definitions of sensitivity above, how sensitive is the asset to:

9. Temporary flooding? No Low Med High Max
10. Permanent flooding? No Low Med High Max
11. Cliff/beach erosion? No Low Med High Max
12. Water table rising? No Low Med High Max
13. Saltwater intrusion/erosion? No Low Med High Max
15. Habitat shifts? No Low Med High Max

16. If the asset is sensitive to any of these exposures, how could exposure impact the asset. For example, % reduction in service, hours of system shutdown; what is the NATURE of the sensitivity?

Please rate the level of adaptive capacity of the asset for each exposure you rated medium, high or maximum. Adaptive capacity is defined as the ability of an asset to recover from the damage or disruption from the elements the asset is exposed to WITHOUT human intervention. Please indicate the level of adaptive capacity for the asset according to these categories:

Maximum Adaptive Capacity: Asset is able to tolerate [impact], no need for intervention.
High Adaptive Capacity: Asset is able to tolerate [impact] and cope with the consequences without the need for significant intervention or modification (e.g., alternate infrastructure routes, elevated structure). Could be easily replaced, repaired.
Medium Adaptive Capacity: Asset is somewhat able to tolerate [impact], and cope with the consequences with significant intervention or modification (repair, replacement are possible).
Low Adaptive Capacity: Asset has limited ability to tolerate [impact], and cope with the consequences (no alternative routes, no restoration possible. Would require replacement or very costly repairs.
No Adaptive Capacity: Asset is not able to tolerate [impact]. Not repairable or replaceable in current location.

Using the definitions above please indicate the asset’s level of adaptive capacity for each of the moderate, high, and maximum sensitivity exposures. [Insert appropriate exposures into the blanks below]

17. No Low Med High Max
18. No Low Med High Max
19. No Low Med High Max

If you rated the asset as having High or Maximum adaptive capacity you are finished with the questionnaire. If you rated the asset as having No, Low, or Medium adaptive capacity, please continue as adaptation may be necessary to ensure the asset avoids destruction and unsafe conditions. The following questions are about potential adaptation considerations and options.

20. What, if any, adaptation or preparation actions have been incorporated into managing the asset for flooding and/or storms?
21. What ideas do you or your agency have for new adaptation or preparation actions?

Physical:

Social:

Financial:

Political:

If no action is taken, sea level rise and storms could have potentially damaging consequences for the asset and those the asset serves. Responses to these question will help prioritize preparation actions for the most sensitive, least resilient assets. While you may not know the answer to each question, please make your best judgment.

22. How important is the asset as an economic generator?
   - very
   - somewhat
   - not
   - $ ______

23. What is the value to the community?
   - high
   - medium
   - low
   - none

24. Does the asset have features that are at-grade or below-grade, e.g., building openings (door, windows, vents) mechanical or electrical equipment, pumps, utilities, building heat, ventilation, power systems or finished basements?
   - no
   - yes, ____________________________

25. What would be the cost to repair/replace the asset?
   - high
   - medium
   - low
   - $ ______

26. How many people could be affected?
   - region
   - community
   - neighborhood
   - site
   - none

27. Are any underrepresented/vulnerable populations affected?
   - no
   - yes, (mark all that apply)
   - People with limited mobility or disability
   - Renters
   - People of color
   - Low income people
   - People over 75 years old
   - Institutionalized populations (hospitals, nursing homes, prisons)
   - Households with limited English proficiency
   - Households lacking vehicle
   - Other ____________________________

28. Are there health impacts?
   - no
   - yes, ____________________________

29. Are there safety impacts?
   - no
   - yes, ____________________________

30. What is the spatial extent or scale of the impact?
   - regional
   - local
   - site
   - less than site

Thank you. This concludes the assessment questions for this asset. Is there anything else you would like to share?

Appendix B: Public Comments

From: Peter Hogg
To: Chris, Chris
Subject: Sea Level Rise Vulnerability
Date: Wednesday, April 26, 2017 11:49 PM

Chris,

Many thanks for your presentation in Mill Valley last night.

The purpose of this email is to clarify the points I raised concerning the use of the words “Greenbrae Boardwalk” in the draft report.

I am a resident of Greenbrae Boardwalk, a community of 46 houses on the edge of Corte Madera Creek directly opposite the Larkspur ferry terminal and east of the railroad trestle. Based on the tables of the number of properties affected by sea level rise it appears that the draft report uses the phrase “Greenbrae Boardwalk” to refer to those portions of the unincorporated community of Greenbrae that are in the flood plain, specifically (1) the houses on Lucky Drive to the west of Highway 101, and (2) the houses on the Greenbrae Boardwalk to the east of Highway 101. These two communities are substantially different in regard to the possible impact of sea level rise.

My suggestion is that you revise the draft report by either (1) replacing the words “Greenbrae Boardwalk” with simply “Greenbrae”, or preferably (2) recognize that the houses on Lucky Drive are more similar to the houses across the water on Riviera Circle than they are to the houses on the Greenbrae Boardwalk. This would of course require significant updates to those tables with entries for “Greenbrae Boardwalk”

If you wish I would be willing to identify by page number what I consider to be misleading information in the draft report concerning the unincorporated area of Greenbrae.

I noted that the 36” impact of the 100-year storm on the sea water elevation is the same number that FEMA used for the height of ‘storm waves’ in Sausalito, Belvedere, and Tiburon in the recently updated FIRM maps. Areas protected from storm waves, e.g., Ross Valley west of Highway 101 would not be subject to the same impact as areas east of Highway 101 (e.g., the Greenbrae Boardwalk). Does your analysis recognize this?

Other sections of the report when describing areas with flood gates, e.g., Bel Marin Keys, stated that the analysis was based on the water elevations when the flood gates were “open”. This would cause a highly misleading analysis particularly because it ignores the effect for which the flood protection measures were installed. Did I misinterpret the report in this respect?

Cheers
Peter

Hello Chris,

In the Larkspur Community Profile section of The Sea Level Rise Vulnerability Assessment Public Review Draft Report, the SLR / Storm Surge map (Map 86) incorrectly shows that the Hillview neighborhood west of BonAir Bridge is shaded in blue which denotes only being affected by a 60" SLR + 100 yr. storm surge. This is incorrect as many residents are currently being flooded by king tides / storm events. Many residents also are required to carry flood insurance *now*. Please compare results against FEMA flood maps and groundtruthing in the area.

Photo: Cornell Avenue, Larkspur during a 2016-2017 winter storm

As Map 86 is revised, the statistics in the chart above it and elsewhere in the report will have to be revised to correctly show the number of residential homes affected.

Please note there are flood mitigation projects being evaluated in the area. But, until such drainage projects & possible pump station are *actually* completed (which may be years down the road, if at all if there is
insufficient funding), the report should show this area very vulnerable. Even if such projects are completed, the nearby levees still need to be raised and improved to protect our area from rising tides and seas. We need to be on the radar so we get funding for levees, etc.

Thank you.
Arlene Fox

http://www.marincounty.org/main/baywave/vulnerability-assessment

All comments below refer to the Draft Larkspur Community Profile of Marin Shoreline Sea Level Rise Vulnerability Assessment Report.

Page 242 & 245: Reference to Heatherwood neighborhood should be replaced with Heather Gardens.

Page 247 / Map 87
Item 2 is incorrectly called Creekside Neighborhood. It's Hillview.

Page 248 Transportation Section & elsewhere
I suggest you include flooding impacts on Bon Air Rd., which serves as a major artery to Marin General Hospital and medical offices on South Eliseo. During January 2017 storm, Bon Air Rd. near Bon Air Bridge was covered with ~1.5 feet of water.

Page 248: Incomplete sentence in third paragraph discussing affected transit routes.

Bullet items which follow, include Bon Air Rd.

Page 251:
In Emergency Services section, CMPD also serves San Anselmo.

In Cultural Resources section, "home" should be "homes".
Thanks Bridgit. I have a proposed markup (attached) that I believe will answer your questions. Please let me know if you have any questions.

Thanks,
Erik

Subject: RE: REMINDER: Marin Sea Level Rise Public Meeting Tomorrow!

Hi Erik:

I looked back and it seems I missed the pump station edit. I'll fix that.

The reclamation lands don't seem vulnerable if they are designed to be “sacrificed,” unless the district would need to locate alternative lands. Would that be the case?

As for the initial comments on elevation, I recall your expert concluding that the assessment is accurate. Do you still have the emails of record?

Thank you,
Bridgit

Subject: RE: REMINDER: Marin Sea Level Rise Public Meeting Tomorrow!

Hi Margaret,

There are still a number of inaccuracies regarding the Novato Sanitary Districts facilities in the report. We have provided previous comments, but not all have been addressed. Will there still be an opportunity to provide comments?

Thanks,
Erik
Novato Sanitary District
The Novato Sanitary District Treatment plant is vulnerable just before 3 feet of sea level rise. By scenario 5, the lower half of the plant is covered by tidal waters. Storm conditions may impact the plant sooner. Much like SASM, the first buildings to be vulnerable are the shops and garages. However, the over flow basins are impacted earlier on. Next to be impacted are the UV Disinfection and Final Effluent Processing buildings. By 5 feet of sea level rise, tides reach the anaerobic digestion and clarification tanks. Adding a storm surge could also flood around the primary and secondary clarifiers altogether. The water will not likely be high enough to impact the process, however, electrical components may be lower and saltwater corrosion of the tanks and buildings could take a toll. The lower half of the plant is bordered by a concrete retaining wall and berm that protect against flood waters. The wall and berm can be extended vertically to provide protection from sea level rise. A 4.5 foot vertical addition to the wall and a 1 foot addition to the berm would protect against scenario 6.

The district also has some facilities in Bel Marin Keys that are transitioning to submersible machines, and others at Grow Field Airport that could be vulnerable to higher tides. However, the more submerged they are, the faster wear and tear could damage the machines.

On-site Waste Water Treatment (OWTS)
The only community in the study area using OWTS is Black Point. However, many of the built areas of these properties are at higher elevations and may be free from impacts from sea level rise. In the worst case, sea level rise could alter soil permeability and chemistry in the disposal field. If water levels are high and still flowing, enough effluent from the disposal field could contaminate the estuary waters. Even new shallow or active ground systems, with high water levels in active ground systems, could be impacted by flood waters and affected by power outages. Erosion could also reduce land area available for percolation. Finally, if ground water rises under septic tanks, it could have enough pressure to cause tanks to pop out of the ground.

These systems are privately managed by the landowner and regulated by Marin County and the Regional Water Quality Control Board. Septic systems are in are regulated by the Marin Countywide Plan (CWP), the Marin County Development Code, and the State Water Control Board's Onsite Wastewater Treatment Systems Policy. More information on regulations can be found at http://www.marincounty.org/departments/environmental-health-services/septic-systems.

Table 37. OWTS System Vulnerabilities

<table>
<thead>

Source: Marin County Environmental Health and Safety

Comment [EB1]: We don't have any shops or garages at the lower end of the plant. Confusing us with the City's Corp Yard?

Comment [EB2]: All pump stations at BMK are submersible type, not transitioning.

Comment [EB3]: MSD does not have any facilities at Grow Field. Our northernmost facility on the east side of 101 is a gravity line that ends at the end of the cul-de-sac of Rush Landing Court.

Comment [EB4]: Suggest striking this paragraph altogether. The statement regarding submersible pumps is inaccurate. The submersible pumps are located in a well with (basically a deep well) that is water tight (no groundwater infiltration). These pump stations are less susceptible than the old-style wet well wetland well pump stations because the electrical components are all above ground. A vulnerability could exist if/when water infiltrates the gravity sewer lines that drain into these pump stations. However, it is unclear from the report if that is a real possibility.
Dear Chris,

Thank you for your hard work leading up the BayWave Vulnerability Assessment. As I said at the Mill Valley public meeting, we want to commend this important effort that is vital to moving all of us closer to solutions for these pressing problems. In particular we would like to commend the thoroughness of the report, especially compared to other counties choosing more of an asset estimate approach. We deeply appreciated that you interviewed Douglas Mondo and Terrie Green for the report and the care you took to analyze the social equity implications of each class of assets and vulnerabilities. We hope there will be future opportunities where you can present results of the assessment in more detail to community members and stakeholders. We appreciate and look forward to continuing our ongoing collaboration with you.

Following is input from Shore Up Marin that we hope you can incorporate into the report:

**Feedback on Executive Summary (HD notes in bold)**

Eight miles of road could expect tidal flooding. Many of these flooded areas already experience seasonal and king tide flooding. These are:
- Manzanita, Almonte
- Miller Avenue in Mill Valley,
- the Marinship area in Sausalito,
- US Highway 101, Corte Madera, Larkspur, and
- State Route 37 in Novato.
- Please add “Marin City / 101 southbound lanes”

Include More on Marin City - note the pipes and flooding impacts of SLR say that’s not in the scope of the tools and study but it is critical to access additional flooding and complimentary data to consider with the vulnerability assessment in adaptation planning.

This is expected to worsen in severity and become increasingly frequent. Tidal flooding would reach the Canal area of San Rafael, spreading to I-580. Several roads in Santa Venetia, Tamalpais, Belvedere, Mill Valley, Marin Lagoon of San Rafael, and bayfront Corte Madera and Larkspur would begin to experience seasonal, king tide, and storm surge flooding more frequently. **Include Marin City / 101 South here.**

Most concerning, however; is the potential inability of emergency professionals and vehicles to access people in or through flooded areas. **(mention Marin City)**

Recommendation: we recommend the County use “real world” measurement for communication with the public e.g. 1 foot 3 inches versus or in addition to 15” because of how people process information, visualize and make meaning out of measurements.
Feedback on the Vulnerability Assessment in general:

The value of assessing vulnerability is in planning to address the real world experience of community members, to prevent emergencies and protect residents and assets. This real world experience includes other factors that are influenced/made more severe by sea level rise, for example the flooding in Marin City/101 which is worsened by tides which block drainage. As you articulated well in the Mill Valley presentation, the limitations of sea level rise models affect all vulnerability assessment. This is why we feel it is critical to include that caveat and include a list of complementary resources and datasets which institutionalize this knowledge and how to best incorporate it in sea level rise planning within the body of the report. This safeguards against many potential challenges which include:

- Future staff changes in which unstated assumptions may not be carried forward,
- Oversimplification of the issues by less topically familiar decision-makers, stakeholders and community members,
- Lack of alignment between hazard mitigation and sea level rise adaptation, and
- Potential under-prioritizing sea level rise adaptation in areas currently most impacted by flooding.

Given that sea level has increased 8 inches over the last century and during the most recent half a century flooding has worsened, is it not logical to point the finger at sea level rise as a key factor? Climate Central cites a 2014 study showing sea level rise as a significant driver of increased flooding, “Long-term trends show that minor coastal flooding along the East, Gulf, and West Coasts occurred only about once every one to five years in the 1950s, but was occurring about once every three months by 2012” [link](http://journals.plos.org/plosone/article?id=10.1371/journal.pone.0170949)

Given that all shoreline areas will experience below ground impacts such as more frequent blockage of drainage pipes, salinization of ground water / bay side agriculture / fresh water marshes, etc. is it not prudent to at least include those concerns and pointers to relevant data sources / best practices as a recommendation for stakeholders to consider? Should we not recommend government staff conduct additional projections to determine the vulnerability of communities when the whole water system is factored in? Here’s Climate Central on sea level rise, storms, flooding, sewers, and East Oakland: [link](http://www.climatecentral.org/news/sea-level-rise-oakland-sewer-17567)

If the twin goals of the vulnerability assessment are to 1. protect the public by encouraging stakeholders to initiate protective projects and 2. to engage community members to understand and support adaptation, we would argue that it undermines community engagement not to include the most severe current flooding that affects the most stakeholders.

We hope you will amend these concerns into the report so communities are not planning based on a world in which sea level rise proceeds independently of other inputs such as watershed flooding, pumps, and the broader water and infrastructure systems.

I hope you will recommend that each entity using the report to move forward with analyzing or implementing solutions will also include community-based knowledge of past flooding.
impacts and patterns, data that is available about streams, creeks and other bodies of water, available FEMA data, and perhaps actuarial data if it is helpful. We hope the report will also include an exhortation and resources to assist readers to stay up to date with the latest mapping tools, research, data and advances in the study of sea level rise, flooding and adaptation.

Thanks again for this opportunity to provide feedback and for your hard work.

Hi Chris,

I just went over the part of the report on sewage agencies and have the following comments. I hope to get to the rest of the report at some time:

1. Doc page 93, was LGVSD inadvertently left off the list??? Or was there a reason?
2. Page 94, first paragraph; Hatches. I don’t think we use that term anywhere. Did some other district?
   It would be helpful to say these “hatches” are at the treatment plants. I at first thought they were referring to manhole covers; not so.
3. Page 96, LGVSD bullet points—“Main Lagoon” should be “Marin Lagoon”

That was it!

400 pages to go... :)

Judy
Chris,

Please see our attached comments from the Greenbrae Improvement Club for the Draft Marin Shoreline Sea Level Rise Vulnerability Assessment. Thank you for your work, and for taking our comments. We look forward to working together on Sea Level Rise on the Adaptability phase.

Jean

Jean Severinghaus
Greenbrae Improvement Club, Chair Environment and Planning Committee
Greenbrae Boardwalk
415-577-3227
Dear Chris Choo,
Thank you for meeting with leadership of the Greenbrae Improvement Club (GIC) and Supervisor Rodoni on May 3rd, 2017, taking our input on the draft Marin Shoreline Sea Level Rise Vulnerability Assessment (SLR Vulnerability Study), and clarifying a number of our questions.

Fred Dupuis, GIC President, Charlie MacDonald, Executive Board Member, and Jean Severinghaus, Chair, Environment and Planning Committee appreciate your making corrections to the conclusions regarding the Greenbrae Boardwalk.

The community would like you to:

a) locate our community correctly, separating out the Lucky Drive homes and the Incorporated Redwood Highway North Larkspur areas from the Greenbrae Boardwalk, and redo all the data tables to reflect the corrections so the SLR Vulnerability Study becomes comprehensible—thank you for agreeing to do that. The Greenbrae Boardwalk is 100% EAST of 101 and has 48 total homes. (Summary Page 305)

b) correct that 100% of our HOUSES (Buildings, pages 302-303) are already elevated, and are generally able to be elevated higher, so are adaptable (not as assumed p.306 on ‘pylons driven deep into the mud’). The recent FEMA Flood map update names the BFE here as 10’—a few homeowners are in the grant application pool to elevate their homes in response. It would be very helpful for the County to be sure the grant program gets followed thru.

c) restate the adaptability of communities residing above living salt-marches to SLR — (see Methods, Phase 3, Adaptive Capacity p. 6)—the salt marshes adapt to daily flooding “without human intervention”, so both the Larkspur Boardwalk One and the Greenbrae Boardwalk PARCELS (Parcels, page 300) vulnerability to flooding should be corrected. The parcels are adaptable. (Please correct also Summary pages 305-306).

In 2016-18 El Nino, we experienced 6” to 12” of increased tide height due to the heat in the ocean, presumably a preview to that much sea level rise, now back to predicted levels. The parcels seemed to be fine and so were the homes despite several flood events.

c1) Utilities, page 322: The GB utilities have been successfully adapted to the past century of sea level rise and salt water intrusion thanks to efforts of the GIC: the gas, electric and water lines are elevated and the sewer is buried with three elevated pumps. The parking lot is raised four feet above Redwood Highway North.

c2) GB appears three times in Table 132—please correct (Page 341)

c3) Marin Park (Page 342) is in incorporated Larkspur and has 350 residents and serves as the City of Larkspur’s Low Income Housing. All of the industrial businesses and mobil homes of Redwood Highway North in Larkspur are currently vulnerable to flooding, and are mainly protected by a few residents of the Greenbrae Boardwalk inflating a dam during storm events. This should be listed. This could be corrected by
raising the GB easements to stop the flooding during tidal events while allowing continued access and staging for the GB in the rest of the times. The dam does not help the GB itself in any way but is a service to the neighborhood.

c4) (Page 312) Do the FEMA damage cost estimates in Table 127 apply to the GB or to both the Lucky Drive, Redwood Hwy North and GB altogether?

c5) Page 308, please correct maps and inserts to separate out GB from Lucky Drive.

d) Please restate the science of living salt marshes with sea level rise. The SLR Vulnerability report should state that salt marshes accrete or rise vertically and adapt to SLR without human intervention. They do so by growing vegetation falling and adding to mud sediments. Storm flood events with landslides and lots of mud in the water are particularly contributory to the continued health of the salt marshes with sea level rise. The boardwalks communities' parcels of land have adapted over the last 100 years of 6” of SLR by accreting vertically (the Greenbrae Boardwalk community has been here since 1903). Aside from being visible under the historic foundations this is documented locally on the adjacent Corte Madera Ecological Reserve (CMER) by two recent US Geological Survey and SF State University mud core, elevation, and sedimentation studies. The salt marsh, if it continues to be protected from the human-caused vulnerabilities of ferry erosion and of removal of natural sediments from Corte Madera Creek and SF Bay, should continue to adapt to SLR for quite some time.

BCDC recognizes the issue of endangering the SF Bay's marshes by over-removal of sediments from the system and is looking to address it. The salt marshes need more sediments now and as sea level rises.

To this point about sediments, how can the nine planned District 9 flood detention basins on the Corte Madera Creek be constructed so as not to remove the storm sediments from the Creek which this and other SF Bay salt marshes critically need as sea level rises?

e) We could use help with study from a hydrologist of the potential vulnerability of the salt marsh to increasing tidal prism as sea level rises: there are six meanders that nourish the marsh. They appear to be deepening and widening and several small new ones are forming. Is there a vulnerability to the buildings along these six meanders and to the survival of the salt marsh with this geomorphologic change? Should they be protected? The unprotected meanders to the north across the creek by the ferry appear to be removing the entire marsh: it is expected to disappear within 20 years.

f) The marsh belonging to the CMER east along the Creek to the Bay entrance facing the ferries is unprotected and has eroded an estimated 50 feet in the past 36 years, with 6’ lost in the past 5 years alone. Once the marsh is gone it’s gone. The face should be protected with some kind of revetment/living shoreline now before SLR worsens the ferry impact. (25 Year Monitoring Study of the revetment shoreline protection project, GGSHTD)
g) The GGBHTD was lead agency and installed a rock revetment shoreline protection in 1989 after nine years of discussions with environmentalists, the BCDC, USACE, CMER and Boardwalk. BCDC documented 12.24 feet of loss of marsh face. The revetment was designed to break up the ferry waves and engine surges at a design height just at the mud-vegetation edge elevation. The revetment has been highly successful per the studies, both in its action as living shoreline protection, healed over by mud and vegetation, supporting the living salt marsh, and by preventing further landward loss of the half mile or so of private properties. The MHHW tidal elevation line in a recent survey approximately follows the top of the rock revetment. Now we have 3 inches of sea level rise at the Golden Gate since the revetment’s installation and its design height is being overtopped. The 25 Year Study above measured elevations on transects: it showed on several transects, where the revetment had been disturbed by the Spartina Removal Project, new erosion as much as 18 feet landward. This would appear to presage a vulnerability that will soon need to be addressed; i.e. renewed ferry erosion of the boardwalk properties and the Corte Madera Ecological Reserve salt marshes behind them as sea level rise overtops the successful protection. The face of the marsh will need to be protected, possibly by simply adding six inches of rock, or another solution, protecting the parcels and the many services the salt marsh provides the larger communities.

In sum, we very much appreciated meeting with you regarding this Vulnerability Study and look forward to working together with you on sea level rise Adaptation issues.

Best wishes,

Fred Dupuis

Dear Ms. Choo,

I’ve spoken to you on a couple of occasions at meetings where you presented the Draft BayWAVE Study to the public. I haven’t done an exhaustive review of the study, but, as I live in Larkspur, I read the separate section pertaining to Larkspur and parts of the larger study, and would like to comment on several things I have concerns about.

I’m concerned that the BayWAVE study may have categorized our home (and those in our boardwalk community) by the same criteria by which the vast majority of homes were assessed, which would yield, in my view, an inaccurate result. Our homes, elevated on fixed piers above a tidal salt marsh, are different from conventional homes, as they are designed to accommodate natural flooding. Corte Madera Creek stormwater and Bay tidal waters flow under our homes, none of which flood. The marsh around us and our lots flood naturally, but our homes do not.

A conventional home’s floor elevations might be at 9.5’ and maybe a foot or so above its surrounding lot. Floor elevations of homes on Larkspur’s Boardwalk One, where I live, are typically in a range above 9.5’ up to maybe 12’ elevation, with surrounding lot elevations of 4-8’ elevation, which is comprised of tidal salt marsh habitat and sloughs/drainage channels. My concern is that the criteria used in the BayWAVE Study, that resulted in our boardwalk homes being judged as highly/immediately vulnerable, were possibly based on low marsh elevations around our homes, rather than, or averaged with, estimated elevations of the homes themselves. Our lots by nature and by definition flood; the boardwalk homes have been here for decades, DO NOT flood, because they’re raised above the surrounding marsh, and can be raised higher. We live WITH floods, not in opposition to them.

I realize higher water from sea level rise and precipitation is coming, to which we will be vulnerable. However, our homes are adaptable in a way that other buildings and homes on Corte Madera Creek are not. On a map that shows future flooding, our homes and boardwalk would be islands, rather than shown as submerged. Our homes can be raised fairly inexpensively, compared to other homes/apartment buildings on the creek, or new foundations that enable flotation. Some examples of other innovative adaptations that make homes more resilient can be found on this website - https://www.niftyhomestead.com/blog/float-ting-homes.

Therefore, I think it’s fair to ask that an explanation be included in the final study that describes the criteria that were used to assess our boardwalk homes. They are THAT unique, such that I don’t think they should be treated or assessed in the same way as conventional buildings. If the criteria used for our home were the same as those for other/conventional homes, which I’m guessing was based on some average of the elevation of our lots and estimated floor elevations, that would not be an accurate assessment, as it makes it look like our HOMES flood, when it’s the properties that flood – by definition. One could argue that Greenbrae Boardwalk homes might be treated separately from conventional homes, as well. Perhaps houseboat communities would also warrant a special set of criteria for vulnerability assessment, as well.
I feel it’s important to comment about this because your document should, if it’s not going to recommend any solutions, at least not discourage thinking of new solutions, by hastily condemning a unique community that happens to be very adaptable to flooding. Our boardwalk community is a potentially resilient example of coexisting WITH future flooding, rather than an example of the most vulnerable to flooding and therefore the first to be destroyed by flooding. A high vulnerability assessment designation may convey automatically that our homes, let alone the marsh habitat we live on, are not worth protecting, buying or insuring, when in actuality, they have much more value being adaptable than most nearby homes along the creek.

I’m asking you to make a note in the BayWAVE study about our community, describing that it is a community uniquely adapted to flooding, similar to a houseboat community, except our homes are fixed, above the tides, and can be raised. The marsh will always be flooded, but our homes can be adapted to rising tides.

SPECIFIC COMMENTS BY PAGE:

P. 242 – Map 86 is not interactive nor “zoomable”, so one cannot see detail. I live within an area that is completely red, a 30-acre area of red – highest vulnerability. That is because it is a marsh. Marshes are vulnerable to flooding, but they also are supposed to flood by definition, and some are resilient, but some will need to be restored and adapted with human help.

p. 242 – “Housing along Corte Madera Creek canals, sloughs, and lagoons could be vulnerable in the near- to medium-terms. This includes, Boardwalk 1, the multi-family units across the canal on Larkspur Plaza, the southern portion of the Heatherwood neighborhood, and some housing west of S. Eliseo Drive.” COMMENT: It’s inaccurate to include Boardwalk One homes in the same category with conventional homes that will flood with no adaptability. Boardwalk One homes are eminently adaptable to living with floods; conventional homes/bldgs. are not.

GENERAL COMMENTS:

1. Not at all meant as criticism, but you may want to know that there are quite a few typos in the draft assessment that hopefully won’t be there in the final.
2. Piper Park Marsh is not named specifically where other marshes ARE NAMED in the BayWAVE Study. “Piper Park” is named, and the marsh is mentioned, but not by name. The reason I mention this is because two partners and I in the Environmental Forum of Marin Master Class, are currently trying to get the City of Larkspur to take stewardship of Piper Park Marsh, which is not currently zoned as open space or marsh conservation. This effort is needed, because several times over the years, the City has tried to fill in parts of the marsh (to create a city corporation yard), and/or the Larkspur Corte Madera School District has proposed installing light poles around the sports field adjacent to the marsh. Boardwalk One residents have objected to both and other actions that compromise the marsh. The City has not assumed stewardship, nor acknowledged that it’s an important asset to the City and its residents. So, calling it by name, Piper Park Marsh, in the BayWAVE study would be a helpful step toward acknowledging it as an important, known asset. My partners and I, as part of an Environmental Forum of Marin project, created the Piper Park Marsh Resiliency Proposal, attached for your perusal, which we are currently working on with the City’s DPW Director, Julian Skinner, and which we will be presenting to the City Council in June.

I commend you on this very thorough and important study, and hope to hear a response to my comments. Question: is this draft study similar to an EIR, in which comments will be incorporated, as written, into the final document, or how are public comments used to improve your final document?

Thank you for your time and dedication, and hopefully in advance for a reply.
